

**TRICYCLIC ANDROGEN RECEPTOR MODULATOR
COMPOUNDS AND METHODS**

Related Application

The present application claims the benefit of priority to U.S. Provisional Application
5 No. 60/271,189, filed on February 23, 2001 which is incorporated by reference in its entirety.

Field of the Invention

This invention relates to non-steroidal compounds that are modulators (*i.e.* agonists,
partial agonists and antagonists) of androgen receptors and to methods for making and using
such compounds.

Background of the Invention

Intracellular receptors (IRs) form a class of structurally-related genetic regulators
scientists have named "ligand dependent transcription factors" (R. M. Evans, *Science*,
240:889, 1988). Sex steroid hormone receptors are a recognized subset of the IRs, including
androgen receptor (AR), progesterone receptor (PR) and estrogen receptor (ER). Regulation
15 of a gene by such factors requires both the receptor itself and a corresponding ligand, which
has the ability to selectively bind to the receptor in a way that affects gene transcription.

The natural hormones for sex steroid receptors have been known for a long time, such
as testosterone for AR and progesterone for PR. A compound that binds to a receptor and
mimics the effect of the native hormone is referred to as an "agonist", while a compound that
20 inhibits the effect of the native hormone is called an "antagonist." The term "modulators"
refers to compounds that are agonists, partial agonists or antagonists.

Synthetic female sex hormones have been widely used in oral contraception, hormone
replacement therapy and the treatment of hormone-dependent disorders. The development of
new generations of selective estrogen receptor modulators (SERMs) significantly improved
25 women's health. On the other hand, similar hormone therapy for men has not been fully
explored due to lack of availability of selective, orally administered, safe agents.

A group of hydroquinoline derivatives was recently described as AR modulators (*e.g.*, U.S. Patent No. 5,696,130). This group of AR modulators was developed by using cell-based high-throughput assays, termed cotransfection assays.

Summary of the Invention

The present invention is directed to tricyclic androgen receptor modulator compounds. This invention is also directed to pharmaceutical compositions containing such compounds as well as methods of using such compounds and pharmaceutical compositions for modulating processes mediated by androgen receptor (AR). More particularly, the invention relates to nonsteroidal compounds and compositions that may be high affinity, high specificity agonists, partial agonists (*i.e.*, partial activators and/or tissue-specific activators) or antagonists for androgen receptor. Also provided are methods of making such compounds and pharmaceutical compositions, as well as intermediates used in their synthesis.

The present invention provides a novel class of AR modulator compounds of the formula:

The compounds of the present invention also include racemates, stereoisomers, optically pure enantiomers and mixtures of said compounds, including isotopically-labeled and radio-labeled compounds. Such isomers can be isolated by standard resolution techniques, including fractional crystallization and chiral column chromatography.

As noted above, the androgen receptor modulator compounds of the present invention can be combined in a mixture with a pharmaceutically acceptable carrier to provide pharmaceutical compositions useful for treating the biological conditions or disorders noted herein in mammalian and particularly in human patients. The particular carrier employed in these pharmaceutical compositions may take a wide variety of forms depending upon the type of administration desired. Suitable administration routes include enteral (*e.g.*, oral), topical, suppository and parenteral (*e.g.*, intravenous, intramuscular and subcutaneous).

In preparing the compositions in oral liquid dosage forms (*e.g.*, suspensions, elixirs and solutions), typical pharmaceutical media, such as water, glycols, oils, alcohols, flavoring

agents, preservatives, coloring agents and the like can be employed. Similarly, when preparing oral solid dosage forms (*e.g.*, powders, tablets and capsules), carriers such as starches, sugars, diluents, granulating agents, lubricants, binders, disintegrating agents and the like may be employed. Due to their ease of administration, tablets and capsules represent a
5 desirable oral dosage form for the pharmaceutical compositions of the present invention.

For parenteral administration, the carrier typically will include sterile water, although other ingredients that aid in solubility or serve as preservatives, may also be included. Furthermore, injectable suspensions may also be prepared, in which case appropriate liquid carriers, suspending agents and the like may be employed.

For topical administration, the compounds of the present invention may be formulated using bland, moisturizing bases, such as ointments or creams. Examples of suitable ointment bases are petrolatum, petrolatum plus volatile silicones, lanolin and water in oil emulsions such as Eucerin™, available from Beiersdorf (Cincinnati, Ohio). Examples of suitable cream bases are Nivea™ Cream, available from Beiersdorf (Cincinnati, Ohio), cold cream (USP), Purpose Cream™, available from Johnson & Johnson (New Brunswick, New Jersey), hydrophilic ointment (USP) and Lubriderm™, available from Warner-Lambert (Morris Plains, New Jersey).

The pharmaceutical compositions and compounds of the present invention generally will be administered in the form of a dosage unit (*e.g.*, tablet, capsule, etc.). The compounds
20 of the present invention generally are administered in a daily dosage of from about 1 µg/kg of body weight to about 500 mg/kg of body weight. Typically, the compounds of the present invention are administered in a daily dosage of from about 10 µg/kg to about 250 mg/kg of body weight. Most often, the compounds of the present invention are administered in a daily dosage of from about 20 µg/kg to about 100 mg/kg body weight. As recognized by those
25 skilled in the art, the particular quantity of pharmaceutical composition according to the present invention administered to a patient will depend upon a number of factors, including, without limitation, the biological activity desired, the condition of the patient and the patient's tolerance for the drug.

The compounds of this invention also have utility when labeled (*e.g.*, radio-labeled, isotopically-labeled and the like) as ligands for use in assays to determine the presence of AR in a cell background or extract. They are particularly useful due to their ability to selectively activate androgen receptors and can therefore be used to determine the presence of such
5 receptors in the presence of other steroid receptors or related intracellular receptors.

These invention methods comprise contacting the cell or cell extract with the compounds of the present invention which have been labeled and testing the contacted cell or cell extract to determine the presence of AR. Testing can be accomplished *via* testing for activation of androgen receptor(s) (*e.g.*, *via* elevated presence of the product of androgen mediated process(es)), *via* separation of the bound compound/receptor combination and the like, which techniques are known to those of skill in the art.
10

Due to the selective specificity of the compounds of this invention for steroid receptors, these compounds can be used to purify samples of steroid receptors *in vitro*. Such purification can be carried out by mixing samples containing steroid receptors with one or more of the compounds of the present invention so that the compounds bind to the receptors of choice and then isolating the bound ligand/receptor combination by separation techniques which are known to those of skill in the art. These techniques include column separation, filtration, centrifugation, tagging and physical separation and antibody complexing, among others.
15

The compounds and pharmaceutical compositions of the present invention can be used in the treatment of the diseases and conditions described herein. In this regard, the compounds and compositions of the present invention may prove particularly useful as modulators of male sex steroid-dependent diseases and conditions such as the treatment of hypogonadism, sexual dysfunction, acne, male-pattern baldness, wasting diseases, hirsutism, prostatic hyperplasia, osteoporosis, impotence, cancer cachexia, various hormone-dependent
20 cancers, including, without limitation, prostate and breast cancer. The compounds of the present invention may also prove useful in male hormone replacement therapy, stimulation of hematopoiesis, male contraception and as anabolic agents.
25

The compounds of the present invention may be extremely potent activators of AR, displaying 50% maximal activation of AR (e.g., activation of AR, determined by measurement of luciferase production levels compared to levels achieved by dihydrotestosterone (DHT)) at a concentration of less than 100 nM (Cotransfection assay concentration), at a concentration of less than 50 nM, at a concentration of less than 20 nM, or even at a concentration of 10 nM or less. (See, for example, Biological Examples.)

Alternatively, the compounds of the present invention may be extremely potent inhibitors of AR, displaying 50% maximal inhibition of AR (e.g., inhibition of AR, determined by measurement of luciferase production levels compared to levels achieved by dihydrotestosterone (DHT)) at a concentration of less than 100 nM (Cotransfection assay concentration), at a concentration of less than 50 nM, at a concentration of less than 20 nM, or even at a concentration of 10 nM or less. (See, for example, Biological Examples.)

In one embodiment, the selective compounds of the present invention generally do not display undesired cross-reactivity with other steroid receptors, as is seen with the compound mifepristone (RU486; Roussel Uclaf), a known PR antagonist that displays an undesirable cross reactivity on GR and AR, thereby limiting its use in long-term, chronic administration.

The invention will be further illustrated by reference to the following non - limiting Examples.

EXAMPLE 112

Steroid Receptor Activity

Utilizing the "cis-trans" or "co-transfection" assay described by Evans et al., Science, 240:889-95 (May 13, 1988), the disclosure of which is incorporated by reference herein, the
5 compounds of the present invention were tested and found to have strong, specific activity as agonists, partial agonists and antagonists of AR. This assay is described in further detail in U.S. Patent Nos. 4,981,784 and 5,071,773, the disclosures of which are incorporated herein by reference.

The co-transfection assay provides a method for identifying functional agonists and
10 partial agonists which mimic, or antagonists which inhibit, the effect of native hormones and quantifying their activity for responsive IR proteins. In this regard, the co-transfection assay mimics an *in vivo* system in the laboratory. Importantly, activity in the co-transfection assay correlates very well with known *in vivo* activity, such that the co-transfection assay functions as a qualitative and quantitative predictor of a tested compounds *in vivo* pharmacology. See,
15 *e.g.*, T. Berger et al. 41 *J. Steroid Biochem. Molec. Biol.* 773 (1992), the disclosure of which is herein incorporated by reference.

In the co-transfection assay, a cloned cDNA for an IR (*e.g.*, human PR, AR or GR) under the control of a constitutive promoter (*e.g.*, the SV 40 promoter) is introduced by transfection (a procedure to induce cells to take up foreign genes) into a background cell
20 substantially devoid of endogenous IRs. This introduced gene directs the recipient cells to make the IR protein of interest. A second gene is also introduced (co-transfected) into the same cells in conjunction with the IR gene. This second gene, comprising the cDNA for a reporter protein, such as firefly luciferase (LUC), controlled by an appropriate hormone responsive promoter containing a hormone response element (HRE). This reporter plasmid
25 functions as a reporter for the transcription-modulating activity of the target IR. Thus, the reporter acts as a surrogate for the products (mRNA then protein) normally expressed by a gene under control of the target receptor and its native hormone.

The co-transfection assay can detect small molecule agonists or antagonists of target IRs. Exposing the transfected cells to an agonist ligand compound increases reporter activity in the transfected cells. This activity can be conveniently measured, *e.g.*, by increasing luciferase production, which reflects compound-dependent, IR-mediated increases in reporter transcription. A partial agonist's activity can be detected in a manner similar to that of the full agonist, except that the maximum measured activity, *e.g.*, luciferase production, is less than that of an agonist standard. For example, for AR, a partial agonist can be detected by measuring increased luciferase production, but the maximum effect at high concentration is less than the maximum effect for dihydrotestosterone. To detect antagonists, the co-transfection assay is carried out in the presence of a constant concentration of an agonist to the target IR (*e.g.*, progesterone for PR) known to induce a defined reporter signal. Increasing concentrations of a suspected antagonist will decrease the reporter signal (*e.g.*, luciferase production). The co-transfection assay is therefore useful to detect both agonists and antagonists of specific IRs. Furthermore, it determines not only whether a compound interacts with a particular IR, but whether this interaction mimics (agonizes) or blocks (antagonizes) the effects of the native regulatory molecules on target gene expression, as well as the specificity and strength of this interaction.

The activity of selected steroid receptor modulator compounds of the present invention were evaluated utilizing the co-transfection assay and in standard IR binding assays, according to the following illustrative Examples.

Co-transfection assay

CV-1 cells (African green monkey kidney fibroblasts) were cultured in the presence of Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% charcoal resin-stripped fetal bovine serum then transferred to 96-well microtiter plates one day prior to transfection.

To determine AR agonist and antagonist activity of the compounds of the present invention, the CV-1 cells were transiently transfected by calcium phosphate coprecipitation

according to the procedure of Berger et al., 41 *J. Steroid Biochem. Mol. Biol.*, 733 (1992) with the following plasmids: pShAR (5 ng/well), MTV-LUC reporter (100 ng/well), pRS- β -Gal (50 ng/well) and filler DNA (pGEM; 45 ng/well). The receptor plasmid, pRShAR, contains the human AR under constitutive control of the SV-40 promoter, as more fully described in J.A. Simental et al., "Transcriptional activation and nuclear targeting signals of the human androgen receptor", 266 *J. Biol. Chem.*, 510 (1991).

The reporter plasmid, MTV-LUC, contains the cDNA for firefly luciferase (LUC) under control of the mouse mammary tumor virus (MTV) long terminal repeat, a conditional promoter containing an androgen response element. See *e.g.*, Berger et al. *supra*. In addition, pRS- β -Gal, coding for constitutive expression of *E. coli* β -galactosidase (β -Gal), was included as an internal control for evaluation of transfection efficiency and compound toxicity.

Six hours after transfection, media was removed and the cells were washed with phosphate-buffered saline (PBS). Media containing reference compounds (*i.e.* progesterone as a PR agonist, mifepristone ((11 β ,17 β)-11-[4-(dimethylamino)phenyl]-17-hydroxy-17-(1-propynyl)estra-4,9-dien-3-one; RU486; Roussel Uclaf) as a PR antagonist; dihydrotestosterone (DHT; Sigma Chemical) as an AR agonist and 2-OH-flutamide (the active metabolite of 2-methyl-N-[4-nitro-3-(trifluoromethyl)phenyl]pronamide; Schering-Plough) as an AR antagonist; estradiol (Sigma) as an ER agonist and ICI 164,384 (N-butyl-3,17-dihydroxy-N-methyl-(7- α ,17- β)-estra-1,3,5(10)-triene-7-undecanamide; ICI Americas) as an ER antagonist; dexamethasone (Sigma) as a GR agonist and RU486 as a GR antagonist; and aldosterone (Sigma) as a MR agonist and spironolactone ((7- α -[acetylthio]-17- α -hydroxy-3-oxopregn-4-ene-21-carboxylic acid γ -lactone; Sigma) as an MR antagonist) and/or the modulator compounds of the present invention in concentrations ranging from 10^{-12} to 10^{-5} M were added to the cells. Three to four replicates were used for each sample.

Transfections and subsequent procedures were performed on a Biomek 1000 automated laboratory work station.

After 40 hours, the cells were washed with PBS, lysed with a Triton X-100-based buffer and assayed for LUC and β -Gal activities using a luminometer or spectrophotometer, respectively. For each replicate, the normalized response (NR) was calculated as:

$$\text{LUC response}/\beta\text{-Gal rate}$$

5 where β -Gal rate = $\beta\text{-Gal} \cdot 1 \times 10^{-5} / \beta\text{-Gal incubation time}$.

The mean and standard error of the mean (SEM) of the NR were calculated. Data was plotted as the response of the compound compared to the reference compounds over the range of the dose-response curve. For agonist experiments, the effective concentration that produced 50% of the maximum response (EC₅₀) was quantified. Agonist efficacy was a
10 function (%) of LUC expression relative to the maximum LUC production by the reference agonist for PR, AR, ER, GR or MR. Antagonist activity was determined by testing the amount of LUC expression in the presence of a fixed amount of DHT as an AR agonist and progesterone as a PR agonist at the EC₅₀ concentration. The concentration of test compound that inhibited 50% of LUC expression induced by the reference agonist was quantified (IC₅₀).
15 In addition, the efficacy of antagonists was determined as a function (%) of maximal inhibition.

IR Binding assay

AR Binding: For the whole cell binding assay, COS-1 cells in 96-well microtiter plates containing DMEM-10% FBS were transfected as described above with the following
20 plasmid DNA: pRShAR (2 ng/well), pRS- β -Gal (50 ng/well) and pGEM (48 ng/well). Six hours after transfection, media was removed, the cells were washed with PBS and fresh media was added. The next day, the media was changed to DMEM-serum free to remove any endogenous ligand that might be complexed with the receptor in the cells.

After 24 hours in serum-free media, either a saturation analysis to determine the K_d
25 for tritiated dihydrotestosterone (³H-DHT) on human AR or a competitive binding assay to evaluate the ability of test compounds to compete with ³H-DHT for AR was performed. For

the saturation analysis, media (DMEM-0.2% CA-FBS) containing ^3H -DHT (in concentrations ranging from 12 nM to 0.24 nM) in the absence (total binding) or presence (non-specific binding) of a 100-fold molar excess of unlabeled DHT were added to the cells. For the competitive binding assay, media containing 1 nM ^3H -DHT and test compounds in concentrations ranging from 10^{-10} to 10^{-6} M were added to the cells. Three replicates were used for each sample. After three hours at 37°C , an aliquot of the total binding media at each concentration of ^3H -DHT was removed to estimate the amount of free ^3H -DHT. The remaining media was removed, the cells were washed three times with PBS to remove unbound ligand and cells were lysed with a Triton X-100-based buffer. The lysates were assayed for amount of bound ^3H -DHT and β -Gal activity using a scintillation counter or spectrophotometer, respectively.

For the saturation analyses, the difference between the total binding and the nonspecific binding, normalized by the β -Gal rate, was defined as specific binding. The specific binding was evaluated by Scatchard analysis to determine the K_d for ^3H -DHT. See e.g., D. Rodbard, "Mathematics and statistics of ligand assays: an illustrated guide" In: J. Langon and J.J. Clapp, eds., *Ligand Assay*, Masson Publishing U.S.A., Inc., New York, pp. 45-99, (1981), the disclosure of which is herein incorporated by reference. For the competition studies, the data was plotted as the amount of ^3H -DHT (% of control in the absence of test compound) remaining over the range of the dose-response curve for a given compound. The concentration of test compound that inhibited 50% of the amount of ^3H -DHT bound in the absence of competing ligand was quantified (IC_{50}) after log-logit transformation. The K_i values were determined by application of the Cheng-Prusoff equation to the IC_{50} values, where:

$$K_i = \frac{\text{IC}_{50}}{(1 + [^3\text{H}\text{-DHT}]) / K_d \text{ for } ^3\text{H}\text{-DHT}}$$

After correcting for non-specific binding, IC₅₀ values were determined. The IC₅₀ value is defined as the concentration of competing ligand needed to reduce specific binding by 50%. The IC₅₀ value was determined graphically from a log-logit plot of the data. The K_i values were determined by application of the Cheng-Prusoff equation to the IC₅₀ values, the labeled ligand concentration and the K_d of the labeled ligand.

The agonist, antagonist and binding activity assay results of selected androgen receptor modulator compounds of present invention and the standard reference compounds on AR, as well as the cross-reactivity of selected compounds on the PR, ER, MR and GR receptors, are shown in Tables 1-2 below. Efficacy is reported as the percent maximal response observed for each compound relative to the reference agonist and antagonist compounds indicated above. Also reported in Tables 1-2 for each compound is its antagonist potency or IC₅₀ (which is the concentration (nM), required to reduce the maximal response by 50%), its agonist potency or EC₅₀ (nM).
